

Lab-5

Task-1

Here we made a priority queue for the specific node. We have to find the shortest distance from a specific node to every node. So made an array to store the weight and then pop the shorter values.

Task-2

Here we have to find a node where both mentioned nodes can meet with minimum time. So we have to use Dijkstra to find the shortest path from both sides, then keep a time tracker and see what time it takes to reach to the specific node from both nodes.

Task 3

Here we have to use Dijkstra but we will not find the shortest path rather we have to find the safest path. For the safest path we have to find the maximum value to reach a specific node. We will hop to next node if weight of the current node is less than the next one.
